Professor William L. Jorgensen
Editor-in-Chief
Journal of Chemical Theory and Computation
American Chemical Society

Dear Professor Jorgensen,

We are pleased to submit our manuscript entitled “Entropic Collapse Model of Molecular Stability: A Self-Referential Thermodynamic Framework” for consideration as a Full Paper in the Journal of Chemical Theory and Computation.

Research Significance

Our paper introduces a novel theoretical framework for understanding and predicting molecular stability that represents a significant advance in theoretical chemistry. The work addresses a fundamental limitation in current thermodynamic approaches: while statistical thermodynamics has been highly successful in describing molecular stability through quantities like Gibbs free energy, it lacks a structural origin for entropy and relies heavily on empirical measurements.

We present a first-principles approach based on a self-referential entropic collapse principle, where molecular stability emerges directly from information-theoretic considerations. Our framework unifies:

1. Quantum decoherence theory

2. Classical thermodynamics
3. Information theory
4. Topological approaches to chemical bonding

through a single mathematical formulation based on the recursive function $\mathcal{E}$ () and our newly defined “collapse entropy” ($E_{collapse}$).

Methodological Innovation

The core innovation of our work is a purely theoretical approach to molecular stability prediction that does not require empirical input. This allows for:

- A priori stability predictions for novel compounds
- Deeper understanding of phenomena like aromaticity and conformational preferences
- A natural bridge between quantum and classical descriptions of molecular systems
- A unified framework applicable across scales from quantum systems to complex biomolecules

Appropriateness for JCTC

We believe this manuscript is ideally suited for JCTC for several reasons:

1. It presents a new theoretical methodology that fundamentally advances our understanding of molecular thermodynamics
2. The framework provides broadly applicable computational approaches rather than system-specific applications
3. It connects quantum chemistry with classical thermodynamics in a novel manner
4. The mathematical foundation is rigorous and builds upon established principles in quantum theory and information science

Data Availability

This paper is entirely theoretical. All mathematical derivations are included either in the main text or the supporting information.

Suggested Reviewers

We suggest the following reviewers who have expertise in theoretical chemistry, quantum information theory, and/or molecular thermodynamics:

1. Dr. Angela Wilson (Michigan State University) - Expert in quantum chemistry and theoretical method development
2. Dr. Martin Head-Gordon (University of California, Berkeley) - Expert in electronic structure theory and theoretical chemistry
3. Dr. Teresa Head-Gordon (University of California, Berkeley) - Expert in computational chemistry and molecular simulation

4. Dr. William Goddard (California Institute of Technology) - Expert in theoretical chemistry and materials simulation
5. Dr. John Perdew (Temple University) - Expert in theoretical method development and quantum theory

Thank you for considering our manuscript. We look forward to your response.

Sincerely,

Haobo Ma, PhD
